Abstract.

Finding interesting association rules is an important and active research field in data mining. The algorithms of the *Apriori* family are based on two rule extraction measures, support and confidence. Although these two measures have the virtue of being algorithmically fast, they generate a prohibitive number of rules most of which are redundant and irrelevant. It is therefore necessary to use further measures which filter uninteresting rules. Many synthesis studies were then realized on the interestingness measures according to several points of view. Different reported studies have been carried out to identify "good" properties of rule extraction measures and these properties have been assessed on 61 measures. The purpose of this paper is twofold. First to extend the number of the measures and properties to be studied, in addition to the formalization of the properties proposed in the literature. Second, in the light of this formal study, to categorize the studied measures. This paper leads then to identify categories of measures in order to help the users to efficiently select an appropriate measure by choosing one or more measure(s) during the knowledge extraction process. The properties evaluation on the 61 measures has enabled us to identify 7 classes of measures, classes that we obtained using two different clustering techniques.

Keywords: Association rule; Interestingness measures; Properties; Clustering.

1. Introduction

Association rules mining algorithms (Agrawal and Srikant, 1994), based on support and confidence measures, tend to generate a large number of rules. These two measures are not sufficient to extract only the really interesting rules and this statement was highlighted in many studies such as (Sese and Morishita, 2002), (Carvalho et al, 2005). An additional step of analyzing extracted rules is therefore essential and different solutions have been proposed. A first solution consists of restoring easily and with a synthetic way, the extracted information through visual representation techniques (Hofmann and Wilhelm, 2001), (Blanchard et al, 2003). A second way is to reduce the number of rules. Some authors (Zaki, 2000), (Zaman Ashrafi et al, 2004), (Ben Yahia et al, 2009) eliminate redundant rules, others evaluate and order the rules due to some interestingness measures (Lenca et al, 2008). In this paper, we focus on the latter path: the use of interestingness measures to eliminate uninteresting rules. Many synthesis studies compared the different objective measures reported in the literature according to several points of view: underlying properties for a "good" interestingness measure (Tan et al, 2002), (Lallich and Teytaud, 2004), (Vaillant, 2006), (Geng and Hamilton, 2007), (Feno, 2007), (Heravi and Zaiane, 2010). These synthetic articles highlighted some of the interestingness measures reported in the literature with some of the proposed properties.

The purpose of this paper is twofold: first to extend the number of the measures and properties to be studied, in addition to the formalization of the different properties proposed in the literature; and second, in the light of this formal study which is performed by the evaluation of interestingness measures according to "good" properties, to categorize the studied measures and to interpret the detected classes. We then wish to detect groups of measures with similar properties, allowing the user from one hand, to restrict the number of measures to choose from, and secondly, to direct his choice based on the properties he wishes that measures check.

Therefore, we want to check classes of measures with similar behavior compared to all the properties we have identified but in any case to explain the properties and measures identified in the literature, explanations can be found in review articles (Tan et al, 2002), (Lallich and Teytaud, 2004), (Vaillant, 2006), (Geng and Hamilton, 2007), (Feno, 2007). The search for these classes of measures was performed using well known techniques as one of the methods of agglomerative hierarchical clustering using Ward criterion (Ward, 1963) and a version of a non-hierarchical clustering method of *k-means* (MacQueen, 1967). A consensus is then derived from the results obtained with both techniques. Before starting the search for classes, it became essential to check that this matrix of *measures* $\times$ *properties* could not be simplified by looking for groups of measures with completely similar behavior in relation to all the *properties* and also, if there was no redundant properties.

The article is thus organized as follows. *Section 3* presents and formalizes the different properties. *Section 4* outlines the matrix of *measures* $\times$ *properties* on which we look for classes and studying if it can not be simplified. *Section 6* restitutes the results of the classification obtained by the first technique: a method of agglomerative hierarchical clustering using Ward criterion. *Section 7* gives the results generated by the second technique: a version of the non-hierarchical clustering method of *k-means* and discusses the consistency of the results obtained by both techniques. The section ends with a consensus classification. Finally,

Section 9 tries to find a semantic to some of the extracted classes and valid the retained classification to those released by (Vaillant, 2006), (Y. Le Bras, 2011), (Huynh et al, 2007), (Lesot and Rifqi, 2010), (Zighed et al, 2011). The article ends with a conclusion and perspectives.

2. Association rules

As defined in (Agrawal et al., 1993), given $I = \{i_1, \dots, i_n\}$ be a set of k items and $B = \{b_1, \dots, b_n\}$ a basket database representing a collection of n subset of items I , an *association rule* (Agrawal et al., 1993) in the database B is a formula

$$X \Rightarrow Y$$

where X and Y are sets of items from I , i.e. $X, Y \subseteq I$ with $X \cap Y = \emptyset$. X represents the antecedent or premise of this rule and Y the consequent or conclusion.

A natural interestingness measure of association rules is based on the notions of support and confidence. The *Support* (when X and Y occur together in at least $s\%$ of the n baskets) and *Confidence* (when from all the baskets containing X , at least $c\%$ also contain Y) of an association rule $X \Rightarrow Y$ are defined by

$$\text{Supp}(X \Rightarrow Y) = \text{Supp}(X \cup Y) \quad \text{and} \quad \text{Conf}(X \Rightarrow Y) = \frac{\text{Supp}(X \cup Y)}{\text{Supp}(X)},$$

An association rule is considered interesting if its confidence and support exceed some user-specified thresholds.

However, the support-confidence approach reveals some weaknesses. Often, this approach as well as algorithms based on it lead to the extraction of an exponential number of rules. Therefore, it is impossible to validate it by an expert. In addition, the disadvantage of the support is that sometimes many rules that are potentially interesting, have a lower support value and therefore can be eliminated by the pruning threshold *minsupp*. To address this problem, many other measures of interestingness have been proposed in the literature (Geng and Hamilton, 2007), mainly because they are effective for mining potentially interesting rules and capture some aspects of user interest. The most important of those measures are subject to our analysis and are surveyed in *Annexe* of section 12. However, the concept of association rule itself as well as various measures of interestingness are particular cases of what is investigated in depth in (Hájek and Havránek, 1978), a book that develops logico-statistical foundations of the GUHA method (Hájek and Holeňa, 2010).

3. Recall and formalization of the properties

The following section presents the different properties of measures reported in the literature. We then recall these properties afterward we formalize them for a better understanding.

This section describes the properties currently used in the literature to characterize measures. Those properties are then summarized in *table 1*.

We give some details about the terminology given in *table 1*:

Table 1. Properties of measures m

N°	Properties
P_1	The measure m is Asymmetric ($P_1(m) = 1$) or symmetric ($P_1(m) = 0$).
P_2	m does not equalize the antinomic rules ($P_2(m) = 1$) or equalizes them ($P_2(m) = 0$).
P_3	m assesses in the same way the rules $X \rightarrow Y$ and $\bar{Y} \rightarrow \bar{X}$ in the logical implication case ($P_3(m) = 1$) or not ($P_3(m) = 0$).
P_4	m increases according to the number of examples ($P_4(m) = 1$) or decreases ($P_4(m) = 0$).
P_5	m increases according to the size of the training set ($P_5(m) = 1$) or not ($P_5(m) = 0$).
P_6	m decreases according to the consequent size ($P_6(m) = 1$) or increases ($P_6(m) = 0$).
P_7	m has a fixed value in the independence case ($P_7(m) = 1$) or not ($P_7(m) = 0$).
P_8	m has a fixed value in the logical implication case ($P_8(m) = 1$) or not ($P_8(m) = 0$).
P_9	m has a fixed value in the equilibrium case ($P_9(m) = 1$) or not ($P_9(m) = 0$).
P_{10}	Identified values in the attraction case between X and Y ($P_{10}(m) = 1$) or not ($P_{10}(m) = 0$).
P_{11}	Identified values in the repulsion case between X and Y ($P_{11}(m) = 1$) or not ($P_{11}(m) = 0$).
P_{12}	m is tolerant to the first counter-examples ($P_{12}(m) = 2$) or not tolerant ($P_{12}(m) = 0$) or indifferent ($P_{12}(m) = 1$).
P_{13}	m invariant in case of expansion of certain quantities ($P_{13}(m) = 1$) or not ($P_{13}(m) = 0$).
P_{14}	m opposes the rules $X \rightarrow Y$ and $\bar{X} \rightarrow Y$ ($P_{14}(m) = 1$) or not ($P_{14}(m) = 0$).
P_{15}	m opposes the antinomic rules $X \rightarrow Y$ and $X \rightarrow \bar{Y}$ ($P_{15}(m) = 1$) or not ($P_{15}(m) = 0$).
P_{16}	m equalizes the rules $X \rightarrow Y$ and $\bar{X} \rightarrow \bar{Y}$ ($P_{16}(m) = 1$) or not ($P_{16}(m) = 0$).
P_{17}	m is based on a probabilistic model ($P_{17}(m) = 1$) or not ($P_{17}(m) = 0$).
P_{18}	m is statistic ($P_{18}(m) = 1$) or descriptive ($P_{18}(m) = 0$).
P_{19}	m is discriminant ($P_{19}(m) = 1$) or not ($P_{19}(m) = 0$).

- **Example:** individual who checks both the premise X and the conclusion Y of the rule,
- **Independence:** case where the realisation of X does not increase the chances of occurrence of Y ,
- **Logical implication:** if the conditional probability $P(Y/X)$ is equal to 1,
- **Equilibrium or indetermination:** case where Y is achieved when there is much chance that X or *not* X be realized,
- **Attraction:** when the realization of X increases the chances of occurrence of Y ,
- **Repulsion:** when the realization of X decreases the chances of occurrence of Y .

We formalize the different properties encountered in the literature and exposed in *table 1*. The title of the 21 properties listed is, preferably, the desired property for a measure m .

Property 1 : Asymmetric measure.

$$\begin{aligned} P_1(m) &= 0 \text{ if } m \text{ is symmetric} && \text{i.e if } \forall X \rightarrow Y \quad m(X \rightarrow Y) = m(Y \rightarrow X) \\ P_1(m) &= 1 \text{ if } m \text{ is not symmetric} && \text{i.e if } \exists X \rightarrow Y \quad / m(X \rightarrow Y) \neq m(Y \rightarrow X) \end{aligned}$$

Property 2 : Asymmetric measure in the sense of the conclusion negation or measure does not equalize the antinomic rules

$$\begin{aligned} P_2(m) &= 0 \text{ if } m \text{ is cn-symmetric} && \text{i.e if } \forall X \rightarrow Y \quad m(X \rightarrow Y) = m(X \rightarrow \bar{Y}) \\ P_2(m) &= 1 \text{ if } m \text{ is not cn-symmetric} && \text{i.e if } \exists X \rightarrow Y \quad / m(X \rightarrow Y) \neq m(X \rightarrow \bar{Y}) \end{aligned}$$

Property 3 : Measure assessing in the same way $X \rightarrow Y$ and $\bar{Y} \rightarrow \bar{X}$ in the logical implication case.

$$\begin{aligned} P_3(m) &= 0 \text{ if } \exists X \rightarrow Y \quad / \quad P(Y/X) = 1 \text{ and } m(X \rightarrow Y) \neq m(\bar{Y} \rightarrow \bar{X}) \\ P_3(m) &= 1 \text{ if } \forall X \rightarrow Y \quad P(Y/X) = 1 \Rightarrow m(X \rightarrow Y) = m(\bar{Y} \rightarrow \bar{X}) \end{aligned}$$

Property 4 : Measure increasing according to the number of examples or decreasing with the number of counter-examples the number of records satisfying X but not Y .

$P_4(m) = 0$ if m didn't increase with n_{XY} i.e. if $\exists X_1 \rightarrow Y_1, \exists X_2 \rightarrow Y_2 /$
 $n_{X_1} = n_{X_2}$ and $n_{Y_1} = n_{Y_2}$ and $(n_{X_1}n_{Y_1} < n_{X_2}n_{Y_2}$ or $n_{X_1}n_{\bar{Y}_1} > n_{X_2}n_{\bar{Y}_2})$
and $m(X_1 \rightarrow Y_1) \geq m(X_2 \rightarrow Y_2)$,

$P_4(m) = 1$ if m is increasing with n_{XY} i.e. if $\forall X_1 \rightarrow Y_1, \forall X_2 \rightarrow Y_2$
 $[n_{X_1} = n_{X_2}$ and $n_{Y_1} = n_{Y_2}$ and $(n_{X_1}Y_1 < n_{X_2}Y_2$ or $n_{X_1}\bar{Y}_1 > n_{X_2}\bar{Y}_2)]$
 $\Rightarrow m(X_1 \rightarrow Y_1) \leq m(X_2 \rightarrow Y_2)$ and
 $[\exists X_1 \rightarrow Y_1, \exists X_2 \rightarrow Y_2] / n_{X_1} = n_{X_2}$ and $n_{Y_1} = n_{Y_2}$ and $(n_{X_1}Y_1 < n_{X_2}Y_2$
or $n_{X_1}\bar{Y}_1 > n_{X_2}\bar{Y}_2)$ and $m(X_1 \rightarrow Y_1) < m(X_2 \rightarrow Y_2)]$

With $n_{XY} = |X \cap Y|$ the number of records satisfying both X and Y and $n_{X\bar{Y}} = |X \cap \bar{Y}|$.

Property 5 : Measure increasing according to the size of the training set n

$P_5(m) = 0$ (m didn't increase with n) if $\exists (\Omega_1, \Omega_2)$,
 $\exists X_1 \rightarrow Y_1 (\Omega_1), \exists X_2 \rightarrow Y_2 (\Omega_2) / n_{X_1} = n_{X_2}$ and $n_{Y_1} = n_{Y_2}$
and $n_{X_1}Y_1 = n_{X_2}Y_2$ and $n_1 < n_2$ and $m(X_1 \rightarrow Y_1) > m(X_2 \rightarrow Y_2)$
 $P_5(m) = 1$ (m increases with n) if $\forall \Omega_1, \forall \Omega_2$,
 $\forall X_1 \rightarrow Y_1 (\Omega_1), \forall X_2 \rightarrow Y_2 (\Omega_2) (n_{X_1} = n_{X_2}$ and $n_{Y_1} = n_{Y_2}$
and $n_{X_1}Y_1 = n_{X_2}Y_2$ and $n_1 < n_2) \Rightarrow m(X_1 \rightarrow Y_1) \leq m(X_2 \rightarrow Y_2)$
and $\exists \Omega_1, \exists \Omega_2, \exists X_1 \rightarrow Y_1 (\Omega_1), \exists X_2 \rightarrow Y_2 (\Omega_2) /$
 $(n_{X_1} = n_{X_2}$ and $n_{Y_1} = n_{Y_2}$ and $n_{X_1}Y_1 = n_{X_2}Y_2$ and $n_1 < n_2)$
and $m(X_1 \rightarrow Y_1) < m(X_2 \rightarrow Y_2)$

Property 6 : Measure decreasing according to the the size of the consequent ¹ or the size of the premise ².

$P_6(m) = 0$ if m didn't decrease with n_Y i.e. if
 $\exists X_1 \rightarrow Y_1, \exists X_2 \rightarrow Y_2 / n_{X_1} = n_{X_2}$ and $n_{X_1}Y_1 = n_{X_2}Y_2$ and $n_{Y_1} < n_{Y_2}$
and $m(X_1 \rightarrow Y_1) < m(X_2 \rightarrow Y_2)$,

$P_6(m) = 1$ if m is decreasing with n_Y i.e. if
 $\forall X_1 \rightarrow Y_1, \forall X_2 \rightarrow Y_2 (n_{X_1} = n_{X_2}$ and $n_{X_1}Y_1 = n_{X_2}Y_2$ and $n_{Y_1} < n_{Y_2})$
 $\Rightarrow m(X_1 \rightarrow Y_1) \geq m(X_2 \rightarrow Y_2)$ and,
 $\exists X_1 \rightarrow Y_1, \exists X_2 \rightarrow Y_2 / (n_{X_1} = n_{X_2}$ and $n_{X_1}Y_1 = n_{X_2}Y_2$ and $n_{Y_1} < n_{Y_2})$
and $m(X_1 \rightarrow Y_1) > m(X_2 \rightarrow Y_2)$

If we consider the premise size, the property $P_6(m) = 1$ is also written:

¹ $n_Y = |Y|$ the number of records satisfying Y .

² $n_X = |X|$ the number of records satisfying X .

$$\begin{aligned}
P_6(m) &= 1 \text{ if } m \text{ is decreasing with } n_x \text{ i.e. when} \\
&\forall X_1 \rightarrow Y_1, \forall X_2 \rightarrow Y_2 \text{ (} n_{Y_1} = n_{Y_2} \text{ and } n_{X_1 Y_1} = n_{X_2 Y_2} \text{ and } n_{X_1} < n_{X_2} \text{)} \\
&\Rightarrow m(X_1 \rightarrow Y_1) > m(X_2 \rightarrow Y_2)
\end{aligned}$$

Property 7 : Fixed value a in the independence case.

$$\begin{aligned}
P_7(m) &= 0 \quad \text{if } \forall a \in \mathbf{R} \quad \exists X \rightarrow Y / P(Y/X) = P(Y) \\
&\quad \text{and } m(X \rightarrow Y) \neq a \\
P_7(m) &= 1 \text{ (fixed value) if } \exists a \in \mathbf{R} / \forall X \rightarrow Y \quad P(Y/X) = P(Y) \\
&\quad \Rightarrow m(X \rightarrow Y) = a
\end{aligned}$$

Property 8 : Fixed value b in the logical implication case.

$$\begin{aligned}
P_8(m) &= 0 \quad \text{if } \forall b \in \mathbf{R} \quad \exists X \rightarrow Y / P(Y/X) = 1 \\
&\quad \text{and } m(X \rightarrow Y) \neq b \\
P_8(m) &= 1 \text{ (fixed value) if } \exists b \in \mathbf{R} / \forall X \rightarrow Y \quad P(Y/X) = 1 \\
&\quad \Rightarrow m(X \rightarrow Y) = b
\end{aligned}$$

Property 9 : Fixed value c in the equilibrium case.

$$\begin{aligned}
P_9(m) &= 0 \quad \text{if } \forall c \in \mathbf{R} \quad \exists X \rightarrow Y / P(Y/X) = P(X)/2 \\
&\quad \text{and } m(X \rightarrow Y) \neq c \\
P_9(m) &= 1 \text{ (fixed value) if } \exists c \in \mathbf{R} / \forall X \rightarrow Y \quad P(Y/X) = P(X)/2 \\
&\quad \Rightarrow m(X \rightarrow Y) = c
\end{aligned}$$

Property 10 : Identified values in the attraction case between X and Y .

$$\begin{aligned}
P_{10}(m) &= 0 \quad \text{if } \forall a \in \mathbf{R} \quad \exists X \rightarrow Y / P(Y/X) > P(Y) \\
&\quad \text{and } m(X \rightarrow Y) \leq a \\
P_{10}(m) &= 1 \text{ (identified values) if } \exists a \in \mathbf{R} / \forall X \rightarrow Y \quad P(Y/X) > P(Y) \\
&\quad \Rightarrow m(X \rightarrow Y) > a
\end{aligned}$$

Property 11 : Identified values in the repulsion case between X and Y .

$$\begin{aligned}
P_{11}(m) &= 0 && \text{if } \forall a \in \mathbf{R} \quad \exists X \rightarrow Y / P(Y/X) < P(Y) \\
&&& \text{and } m(X \rightarrow Y) \geq a \\
P_{11}(m) &= 1 && \text{(identified values) if } \exists a \in \mathbf{R} / \forall X \rightarrow Y \quad P(Y/X) < P(Y) \\
&&& \Rightarrow m(X \rightarrow Y) < a
\end{aligned}$$

Property 12 : Tolerance to the first counter-examples.

$$\begin{aligned}
P_{12}(m) &= 0 && \text{if reject so convex, } \exists \min_{conf} \in [0, 1] / \forall X_1 \rightarrow Y_1, \forall X_2 \rightarrow Y_2 \\
&&& \forall \lambda \in [0, 1] \quad n_{X_1 Y_1} \geq \min_{conf} n(X_1) \quad \text{and} \quad n_{X_2 Y_2} \geq \min_{conf} n(X_2) \\
&&& \Rightarrow f_{m, n_{XY}}(\lambda n_{X_1 Y_1} + (1 - \lambda) n_{X_2 Y_2}) \leq \lambda f_{m, n_{XY}}(n_{X_1 Y_1}) + (1 - \lambda) f_{m, n_{XY}}(n_{X_2 Y_2}) \\
P_{12}(m) &= 1 && \text{if indifference then linear i.e. } P_{14}(m) \neq 0 \quad \text{and} \quad P_{14}(m) \neq 2 \\
P_{12}(m) &= 2 && \text{if tolerance then concave } \exists \min_{conf} \in [0, 1] / \forall X_1 \rightarrow Y_1, \forall X_2 \rightarrow Y_2, \\
&&& \forall \lambda \in [0, 1] \quad n_{X_1 Y_1} \geq \min_{conf} n(X_1) \quad \text{and} \quad n_{X_2 Y_2} \geq \min_{conf} n(X_2) \\
&&& \Rightarrow f_{m, n_{XY}}(\lambda n_{X_1 Y_1} + (1 - \lambda) n_{X_2 Y_2}) \geq \lambda f_{m, n_{XY}}(n_{X_1 Y_1}) + (1 - \lambda) f_{m, n_{XY}}(n_{X_2 Y_2})
\end{aligned}$$

The notation $f_{m, n_{XY}}$ corresponds to the evolution according to the measure m with n_{XY} when n_X , n_Y and n remain constant.

Property 13 : Invariance in case of expansion of certain quantities
(n_{XY} , $n_{\bar{X}Y}$ and $n_{X\bar{Y}}$).

$$\begin{aligned}
P_{13}(m) &= 0 && \text{(variance) if } \exists (k_1, k_2) \in N_{*2}, \exists X_1 \rightarrow Y_1, \exists X_2 \rightarrow Y_2 / \\
&&& [n_{X_1 Y_1} = k_1 n_{X_2 Y_2} \text{ and } n_{X_1 \bar{Y}_1} = k_1 n_{X_2 \bar{Y}_2} \text{ and } n_{\bar{X}_1 Y_1} = k_2 n_{\bar{X}_2 Y_2} \text{ and } n_{\bar{X}_1 \bar{Y}_1} = k_2 n_{\bar{X}_2 \bar{Y}_2} \\
&&& \text{and } m(X_1 \rightarrow Y_1) \neq m(X_2 \rightarrow Y_2)] \text{ or} \\
&&& [n_{X_1 \bar{Y}_1} = k_1 n_{X_2 \bar{Y}_2} \text{ and } n_{\bar{X}_1 \bar{Y}_1} = k_1 n_{\bar{X}_2 \bar{Y}_2} \text{ and } n_{X_1 Y_1} = k_2 n_{X_2 Y_2} \text{ and } n_{\bar{X}_1 Y_1} = k_2 n_{\bar{X}_2 Y_2} \\
&&& \text{and } m(X_1 \rightarrow Y_1) \neq m(X_2 \rightarrow Y_2)] \\
P_{13}(m) &= 1 && \text{(invariance) if } \forall (k_1, k_2) \in N_{*2}, \forall X_1 \rightarrow Y_1, \forall X_2 \rightarrow Y_2 / \\
&&& [(n_{X_1 Y_1} = k_1 n_{X_2 Y_2} \text{ and } n_{X_1 \bar{Y}_1} = k_1 n_{X_2 \bar{Y}_2} \text{ and } n_{\bar{X}_1 Y_1} = k_2 n_{\bar{X}_2 Y_2} \text{ and } n_{\bar{X}_1 \bar{Y}_1} = k_2 n_{\bar{X}_2 \bar{Y}_2}) \\
&&& \Rightarrow m(X_1 \rightarrow Y_1) = m(X_2 \rightarrow Y_2)] \text{ and} \\
&&& [(n_{X_1 \bar{Y}_1} = k_1 n_{X_2 \bar{Y}_2} \text{ and } n_{\bar{X}_1 \bar{Y}_1} = k_1 n_{\bar{X}_2 \bar{Y}_2} \text{ and } n_{X_1 Y_1} = k_2 n_{X_2 Y_2} \text{ and } n_{\bar{X}_1 Y_1} = k_2 n_{\bar{X}_2 Y_2}) \\
&&& \Rightarrow m(X_1 \rightarrow Y_1) = m(X_2 \rightarrow Y_2)]
\end{aligned}$$

It is important to note that the formalization of this property by (Tan et al, 2002) with the help of the matrix is more compact than what we present, but in this article we are looking for the same formalization for all the properties.

Property 14 : Desired Relationship between the rules $X \rightarrow Y$ and $\bar{X} \rightarrow Y$.

$$P_{14}(m) = 0 \text{ if } \exists X \rightarrow Y / m(\bar{X} \rightarrow Y) \neq -m(X \rightarrow Y)$$

$$P_{14}(m) = 1 \text{ if } \forall X \rightarrow Y \quad m(\bar{X} \rightarrow Y) = -m(X \rightarrow Y)$$

Property 15: Desired Relationship between the antinomic rules $X \rightarrow Y$ and $X \rightarrow \bar{Y}$.

$$P_{15}(m) = 0 \text{ if } \exists X \rightarrow Y / m(X \rightarrow \bar{Y}) \neq -m(X \rightarrow Y)$$

$$P_{15}(m) = 1 \text{ if } \forall X \rightarrow Y \quad m(X \rightarrow \bar{Y}) = -m(X \rightarrow Y)$$

Property 16: Desired relationship between the rules $X \rightarrow Y$ and $\bar{X} \rightarrow \bar{Y}$.

$$P_{16}(m) = 0 \text{ if } \exists X \rightarrow Y / m(\bar{X} \rightarrow \bar{Y}) \neq m(X \rightarrow Y)$$

$$P_{16}(m) = 1 \text{ if } \forall X \rightarrow Y \quad m(\bar{X} \rightarrow \bar{Y}) = m(X \rightarrow Y)$$

Property 17: Premise size is fixed or random.

$$P_{17}(m) = 0 \text{ (fixed size) if } m \text{ isn't established on a probabilistic model}$$

$$P_{17}(m) = 1 \text{ (random size) if } m \text{ is established on a probabilistic model}$$

Property 18: Descriptive or statistical measure.

$$P_{18}(m) = 0 \text{ (descriptive or invariant) if } \forall k \in N^*, \forall X_1 \rightarrow Y_1, \forall X_2 \rightarrow Y_2,$$

$$(n_{X_1 Y_1} = kn_{X_2 Y_2} \text{ and } n_{X_1 \bar{Y}_1} = kn_{X_2 \bar{Y}_2} \text{ and } n_{\bar{X}_1 Y_1} = kn_{\bar{X}_2 Y_2} \text{ and } n_{\bar{X}_1 \bar{Y}_1} = kn_{\bar{X}_2 \bar{Y}_2})$$

$$\Rightarrow m(X_1 \rightarrow Y_1) = m(X_2 \rightarrow Y_2)$$

$$P_{18}(m) = 1 \text{ (statistical) if } \exists k \in N^*, \exists X_1 \rightarrow Y_1, \exists X_2 \rightarrow Y_2 / (n_{X_1 Y_1} = kn_{X_2 Y_2}$$

$$\text{and } n_{X_1 \bar{Y}_1} = kn_{X_2 \bar{Y}_2} \text{ and } n_{\bar{X}_1 Y_1} = kn_{\bar{X}_2 Y_2} \text{ and } n_{\bar{X}_1 \bar{Y}_1} = kn_{\bar{X}_2 \bar{Y}_2})$$

$$\text{and } m(X_1 \rightarrow Y_1) \neq m(X_2 \rightarrow Y_2)$$

Property 19: Discriminant measure.

$$P_{19}(m) = 0 \text{ (non discriminant) if } \exists \eta \in N^* / \forall n > \eta \forall X_1 \rightarrow Y_1, \forall X_2 \rightarrow Y_2$$

$$[P(Y_1/X_1) > P(Y_1) \text{ and } P(Y_2/X_2) > P(Y_2)] \Rightarrow m(X_1 \rightarrow Y_1) \simeq m(X_2 \rightarrow Y_2)$$

$$P_{19}(m) = 1 \text{ (statistical) if } \forall \eta \in N^* \exists n > \eta \exists X_1 \rightarrow Y_1 \exists X_2 \rightarrow Y_2 /$$

$$[P(Y_1/X_1) > P(Y_1) \text{ and } P(Y_2/X_2) > P(Y_2)] \text{ and } m(X_1 \rightarrow Y_1) \neq m(X_2 \rightarrow Y_2)$$

After formalizing the properties, we will study them on the different objectives measures.

4. Evaluation of properties on measures

This section looks for different objective interestingness measures, the presence or absence of the properties identified in *Section ??* and formalized in *Section ??*. This work will lead to the construction of a measure-property matrix.

We examined 69 measures of which 46 are from synthesis work (Piatetsky-Shapiro, 1991), (Tan et al, 2002), (Lallich and Teytaud, 2004), (Geng and Hamilton, 2007), (Vaillant, 2006) and (Feno, 2007). Nine measures described in (Huynh et al, 2005) have also been studied. These measures include: *Causal confidence*, *Causal confirmed confidence*, *Descriptive confirmed confidence*, *Causal confirmation*, *Descriptive confirmation*, *Dependency*, *Putative causal dependency*, *Pavillon* and *Causal support*.

Finally, the remaining measures are the following: *Czekanowski-Dice* (Czekanowski, 1913), *Fukuda* (Fukuda et al, 1996), *Ganascia* (Ganascia, 1987), *probabilistic index of deviation from equilibrium* (Blanchard et al, 2005), *probabilistic index of deviation from the entropic equilibrium* (Blanchard et al, 2005), *entropic intensity of implication* (Gras et al, 2001), *likelihood link index* (Lerman and Azé, 2007), *Kappa* (Cohen, 1960), *Kulczynski* (Kulczynski, 1928), *MGK* (Guillaume, 2000), *Ochiai* (Ochiai, 1957), *satisfaction* (Lavrac et al, 1999) and *VT100* (Rakotomalala and Morineau, 2008).

Through the study of these different measures, we detect the presence of measures having the same definition but different names and are as follows:

- { φ – coefficient or *Correlation coefficient*};
- {*Cohen* or *Kappa*};
- {*Centred confidence* or *Added value* or *Pavillon*};
- {*Descriptive-confirmed confidence* or *Ganascia*};
- {*Cosine* or *Ochiai*};
- {*Czekanowski-Dice* or *F-measure*};
- {*Bayes factor* or *Odd-multiplier*};
- {*Factor of certainty* or *Satisfaction* or *Loevinger*};
- {*Kulczynski* or *Agreement and disagreement index*};
- {*Support* or *Russel and Rao index*};
- {*Accuracy* or *Causal support*}.

Therefore, if we keep only one measure from the ones listed above, we will be in the presence of 61 measures. *Table 2* summarizes and groups them into two categories: symmetrical and asymmetrical measures. The definition of each index is available in *Appendix 1* in *table 6*. The 61 measures of the table are ordered alphabetically, the number of measures given in the table facilitates the search for its definition. After presenting data on which we will achieve a classification, we now ensure that they can not be constrained by searching for groups of measures with identical behavior and if properties are not redundant.

Initially, we searched all measures whose values for each of the 19 properties are identical. We found the following seven groups: $G_1 = \text{correlation coefficient, novelty}$, $G_2 = \text{Causal confidence, Causal-confirm confidence, Negative reliability,}$

$G_3 = \text{Cosine}$, Czekanowski-Dice , $G_4 = \text{Causal dependency}$, Leverage , Specificity , $G_5 = \text{Collective strength}$, Odds ratio , $G_6 = \text{Gini}$, $\text{Mutual information}$ and $G_7 = \text{Jaccard}$, Kulczynski .

Following the detection of these seven groups of measures, we are now in the presence of a matrix of 52 measures since we retain only one measure from each one.

By looking if properties are not redundant, we investigated whether a property had identical values with another property for each of the 52 measures. We haven't found such relationship.

5. Categorization

Actually, we are in the presence of a matrix of 52 measures and 19 properties, properties that are nominal qualitative variables. Nevertheless, it's not easy for data mining experts to choose the appropriate interestingness measure from a set of 52 measures. Therefore, it is frequently necessary to identify groups of measures with similar properties to help the user capture the most suitable ones. The most commonly used technique for finding such relationships is cluster analysis (Fayyad et al., 1996), (Hartigan, 1975).

Clustering techniques are generally used in an unsupervised fashion. They are used to place data elements into several groups such that elements in the same group are close to each others and elements across groups are far from each others (Duda and Hart, 1973). However, there exist many efficient clustering algorithms in the data mining literature among which the well-known and used are *k-means* clustering and Agglomerative Hierarchical Clustering (*AHC*). Choosing one of those techniques is not an easy task, if each of them has advantages and limitations.

5.1. *K-means* technique

K-means clustering (MacQueen, 1967) is a commonly used method (Bradley et al., 1998), (Fanstrom et al., 2000), (Roweis and Ghahramani, 1999) of cluster analysis which aims to automatically partition observations into k groups of greatest possible distinction, where k is provided as an input parameter. It is an iterative aggregation method which, wherever it starts from, converges on a solution. *K-means* has several advantages. It is simple and fast: with a large number of variables, it may be computationally faster than hierarchical clustering (when k is small). In addition, any element may be assigned to a group during one iteration then change from group in the following iteration, which is not possible with *AHC* for which assignment is irreversible.

Despite these advantages, the fixed number of clusters that *k-means* clustering technique require to specify as an input, can make it difficult to predict the appropriate number of clusters k . Then, an inappropriate choice of k may yield to poor results. Another disadvantage to using this technique is the possibility of multiplying the starting locations of cluster centers, which yield to several solutions and multiple clusterings. The solution obtained is not necessarily the same for all starting points.

5.2. AHC technique

In data mining, hierarchical clustering (Ward, 1963) is a one of the most frequently method of cluster analysis which seeks to build a hierarchy of clusters. Agglomerative hierarchical clustering (Guha et al., 1998), (Guha et al., 2000), (Karypis et al., 1999), (King, 1967), (Sneath and Sokal, 1973) is a "bottom-up" clustering method where each observation starts in its own cluster, and pairs of clusters are merged as one moves up the hierarchy. Hierarchical clustering solutions, which are in the form of trees called dendrograms, are of great interest for a number of application domains. Despite its proven utility, hierarchical clustering has many flaws: e.g., interpretation of the hierarchy is complex and often confusing; the use of different distance metrics for measuring distances between clusters may generate different results. Nevertheless, it is also essential to recognize the advantages of AHC, if it can produce an ordering of the elements, which may be informative for data display. Smaller clusters are generated, which may be helpful for discovery.

The importance revealed by the agglomerative hierarchical clustering and *k-means* clustering techniques, encourage us to apply both of them on our measure-property matrix in order to come out with a consensus.

To launch two versions of clustering algorithms, versions require binary variables, we perform a complete disjunctive encoding, which leads us to obtain 39 binary variables. So we have finally a matrix of 52 measures $\times$ 39 binary variables.

After discussing the data and converted them to be able to apply the selected algorithms, we study the first clustering of measures obtained with a method of hierarchical cluster analysis.

6. Classification obtained by AHC method

We made an agglomerative hierarchical classification with *Matlab* software on these 52 measures using Euclidean distance between pairs of measures then Ward distance for the aggregation phase. *Figure 1* restitues this classification for Ward distance. As the loss of interclass inertia must be as small as possible, we cut the dendrogram at a level where branch height is high, corresponding to the dendrogram colored branches.

We might also choose the Manhattan distance and we would obtain similar results because the matrix is essentially binary: 18 of 19 binary variables, and in this case, Manhattan distance is the squared Euclidean distance. Only one variable has *three* values: property *P₁₂*.

This classification reveals the 8 following groups of measures:

- $Gc_1 = \{\textit{Likelihood index link}, \textit{Intensity of implication (II)}\}$
- $Gc_2 = \{\textit{REII}, \textit{EII}, \textit{PDI}, \textit{IP3E}, \textit{IPEE}\}$
- $Gc_3 = \{\textit{Two-way variation Support}, \textit{Pearl}\}$
- $Gc_4 = \{\textit{Implication index}, \textit{Fukuda}, \textit{Gini}, \textit{J-measure}, \textit{Dependency}, \textit{Weighted dependency}, \textit{Prevalence}, \textit{Coverage}\}$
- $Gc_5 = \{\textit{VT100}, \textit{Accuracy}, \textit{Jaccard}, \textit{Support}, \textit{Cosine}, \textit{Recall}, \textit{Causal dependency}, \textit{Causal confirm}, \textit{Causal confidence}\}$

Symmetric measures			
1	correlation coefficient	2	Cohen or Kappa
11	Cosinus or Ochiai	13	Czekanowski
20	Collective strength	22	Informationnel gain
24	Goodman	33	Likelihood index
34	interest	35	Jaccard
38	Kulczynski	43	Novelty
44	Pearl	45	Piatetsky-Shapiro
46	Accuracy	48	Yule's Q
50	Odds ratio	54	Support
56	One way support	58	VT100
59	Support variation	60	Yule's Y
Asymmetric measures			
3	Confidence	4	Causal confidence
5	Pavillon	6	Ganascia
7	Causal-confirm confidence	8	Causal confirm
9	Descriptive confirm	10	Conviction
12	Coverage	14	Dependency
15	Causal dependency	16	Weighted dependency
17	Bayes factor	18	Factor of certainty or Loevinger
19	Negative reliability	21	Fukuda
23	Gini	25	Implication index
26	Probabilistic intensity of deviation from equilibrium (IPEE)	27	Entropic probabilistic intensity of deviation from equilibrium (IP3E)
28	Probabilistic discriminant index (PDI)	29	Mutual information
30	Intensity of Implication (II)	31	Entropic intensity of implication (EII)
32	Entropic intensity of revised implication (REII)	36	J-measure
37	Klogsen	39	Laplace
40	Leverage	41	MGK
42	Least contradiction	47	Prevalence
49	Recall	51	Relative risk
52	Sebag-Schoenauer	53	Specificity
55	One way support	57	Examples rate
61	Zhang		

Table 2. Studied measures

Fig. 1. Agglomerative hierarchical clustering using Ward criterion

- $G_{C_6} = \{\text{Sebag, Least contradiction, Descriptive confirmation, Examples rate, Ganascia, Laplace, Confidence}\}$
- $G_{C_7} = \{\text{Zhang, MGK, Yule's Y, Yule's Q, Goodman, Piatetsky-Shapiro, Correlation coefficient}\}$
- $G_{C_8} = \{\text{Interest, Informational gain, Collective strength, Cohen, Relative risk, Bayesian factor, Conviction, Factor of certainty, Pavilion, Klosgen, Two-way support, One-way support}\}$

After making this initial measures classification, we will compare it with the

classification revealed by the second technique of the k -means method afterwards we discuss the different results obtained in order to reach a consensus.

7. Classification obtained by a version of k -means

We performed a partitioning method with k -means using *Matlab* software by retaining equally the Euclidean distance. We chose *eight* classes according to the results of the *AHC* and we obtained the following partitioning. While presenting these *eight* new classes obtained, we discuss the consistency of the results obtained with the first technique.

- $Gp_1 = \{\textit{Likelihood index link}, \textit{Intensity of implication (II)}, \textit{REII}\}$
This group is very close to the group Gc_1 since we have $Gp_1 = Gc_1 \cup \{\textit{REII}\}$.
- $Gp_2 = \{\textit{EII}, \textit{PDI}, \textit{IP3E}, \textit{IPEE}\}$
This group is very close to the group Gc_2 since we have $Gp_2 = Gc_2 - \{\textit{REII}\}$. We have the following equality: $Gp_1 \cup Gp_2 = Gc_1 \cup Gc_2$, which shows some consistency in the obtained results since we are in the presence of all indices of the likelihood link family.
- $Gp_3 = \{\textit{Two-way variation Support}, \textit{Pearl}, \textit{Implication index}, \textit{Gini}, \textit{J-measure}, \textit{Dependency}, \textit{Prevalence}, \textit{Coverage}\}$
This group is close to the group Gc_4 since we have:
 $Gp_3 = Gc_3 \cup Gc_4 \cup \{\textit{Fukuda}, \textit{Weighted dependency}\}$. It should be noted that Gc_3 group, which is composed by *Two-way variation Support* and *Pearl* measures, is the closest group to Gc_4 (see dendogram in figure 1).
- $Gp_4 = \{\textit{Accuracy}, \textit{Jaccard}, \textit{Support}, \textit{Cosine}, \textit{Recall}, \textit{Causal dependency}, \textit{Causal confirm}, \textit{Causal confidence}\}$
This group is similar to Gc_5 group since we have:
 $Gp_4 = Gc_5 \cup \{\textit{Fukuda}, \textit{Weighted dependency}\} - \{\textit{VT100}\}$.
- $Gp_5 = \{\textit{Sebag}, \textit{Least contradiction}, \textit{Descriptive confirmation}, \textit{Fukuda}\}$
This group is identical to Gc_6 group.
- $Gp_6 = \{\textit{Zhang}, \textit{MGK}, \textit{Yule's Y}, \textit{Yule's Q}\}$
This group is similar to Gc_7 group since we have: $Gc_7 = Gp_6 \cup \{\textit{Piatetsky-Shapiro}, \textit{Correlation coefficient}\}$
- $Gp_7 = \{\textit{Interest}, \textit{Informational gain}, \textit{Relative risk}, \textit{Bayes factor}, \textit{Conviction}, \textit{Certainty factor}, \textit{Pavilion}, \textit{Klosgen}, \textit{Two-way support}, \textit{One-way support}\}$
The group Gp_7 is very close to Gc_8 group since we have 10 of 12 measures in common. We have the following equality: $Gc_8 = Gp_7 \cup \{\textit{Collective strength}, \textit{Cohen}\}$.
- $Gp_8 = \{\textit{VT100}, \textit{Piatetsky-Shapiro}, \textit{Correlation coefficient}, \textit{Collective strength}, \textit{Cohen}\}$
Unlike other groups $Gp_i (i = \{1, \dots, 7\})$, this group is not similar to any of the $Gc_j (j = \{1, \dots, 8\})$ groups, since these *five* measures are from Gc_5 , Gc_7 and Gc_8 groups.

A consensus on the classification is presented in the following.

Fig. 2. Clusters of measures.

8. Final classification

After the discussion about the consistency of the results obtained by both techniques, we derive a consensus on the classification. *Figure 2* shows the consensus and restores the classes C₁ to C₇ of the common extracted measures to both techniques. We also include measures for which no consensus has been found and give, where it is possible, the two measures membership groups (or classes). We have labeled the arrows by "c" and "p" to indicate which technique gathered the measures in the pointed group (*c* = *hierarchical clustering* or *p* = *partitioning* or *non hierarchical clustering*). Finally, in the lower center of the figure, we recall the same measures but with different names.

Having summarized the results obtained (*Figure 2*), we try in the next section to give a semantic to certain extracted classes and validate this classification with those released by (Vaillant, 2006), (Lesot and Rifqi, 2010), (Zighed et al, 2011).

9. Clusters review and validation

It is not easy to give a semantic to each of the extracted classes by looking only the definitions of these measures. Two classes are yet easy to interpret, which are

C_1 and C_2 classes where we find all the indices of the likelihood link index family (Lerman, 1970), the founder index. C_1 class has original indices: the likelihood link index and intensity of implication (II) (Gras, 1979). We know that these two measures are very close since the likelihood link index searches if examples number (those who hold both the premise and conclusion) is significantly higher while Intensity of implication assesses whether the counter-examples number (those that satisfy the premise but does not verify the conclusion) is significantly low.

For C_2 class, we find the Entropic implication intensity (EII (Gras et al, 2001) and IP3E (Blanchard et al, 2005)) measures with the probabilistic index of deviation from equilibrium (IPEE (Blanchard et al, 2005)) and the probabilistic discriminant index PDI (Lerman and Az, 2007). These measures are derived from a common idea: to assess the significance of a number (number of examples or counter-examples), combining for some measures (REII (Lallich et al, 2005), EII, IP3E) with an entropic index so that the measure is discriminant in the case of large data. As for PDI, this index normalizes Intensity of implication in order that the latter be discriminant in the case of large data by evaluating a rule with respect to the set of valid rules.

To try to explain each of these classes $C_i (i = 1, \dots, 7)$, in *table 3*, we summarize all the properties satisfied by each of the seven classes. We add a symbol to the original matrix, the "?" character, which has the meaning "*unknown*" that is to say that measures of class C_i take different values for the concerned property $P_j (j = 1, \dots, 19)$. In case where the property is a contradicted once, we show the majority property value. Then "0" means that all the measures of the C_i class except one measure, take the value "0" for the property P_j .

By summarizing all the properties satisfied by each of the seven classes in this table, we help the user in the selection of his measure(s) since he/she has only to read a much smaller matrix than the original. Moreover, if he/she wishes very different measures, his/her choice is also facilitated with the consultation of this table, help has been complemented by the dendrogram shown in the figure where a notion of proximity between measures appears. Finally, this classification can also help to choose measures that are too similar to avoid taking clues from the same class.

About finding semantic for each class, this synthetic table can be a support to an interpretation as we will illustrate it for C_4 and C_6 classes. We will therefore focus on these classes and try to give an interpretation. We start with the class C_6 .

9.1. C_6 class study

C_6 class is composed of five measures: Zhang (Zhang, 2000), MGK (Guillaume, 2000), Y and Q of Yule (Yule, 1900) and Goodman (Tan et al, 2002). We know from the table that they satisfy the following properties:

- Non symmetry in the sense of conclusion negation ($P_2 = 1$),
- Identical evaluation in the logical implication case ($P_3 = 1$),
- Growth according to the number of examples ($P_4 = 1$),
- Growth according to the data size ($P_5 = 1$),
- Fixed value in the independence case ($P_7 = 1$),
- Fixed value in the logical implication case ($P_8 = 1$),

Prop\Clusters	C_1	C_2	C_3	C_4	C_5	C_6	C_7
P_1	?	1	1	?	1	?	?
P_2	1	1	?	1	1	1	1
P_3	1	1	0?	?	?	1	?
P_4	1	1	0	1?	1	1	?
P_5	1	0?	0	?	0	1	1
P_6	1	1?	0	1?	0	0	1?
P_7	1	0	?	0	0	1	1
P_8	0	0	0	?	?	1	0?
P_9	0	?	0	0	1	0	0
P_{10}	1	0	0?	0	0	1	1
P_{11}	1	0	0	0	0	1	1
P_{12}	2	2	?	?	?	?	?
P_{13}	?	0?	0	0	0	?	0?
P_{14}	0	0	0	0	0	?	0
P_{15}	0	0	0	0	?	1	0?
P_{16}	0	0	?	0?	0	?	0
P_{17}	1	1	0	0	0	0	0
P_{18}	1	1	0?	0	0	0	0
P_{19}	0	1?	?	1	1?	1	1

Table 3. Characteristics of the seven detected classes

- Identifiable values when the realization of the premise increases the chances of occurrence of the conclusion ($P_{10} = 1$),
- Identifiable values when the realization of the premise reduces the chances of occurrence of the conclusion ($P_{11} = 1$),
- Opposed values for the antinomic rules $X \rightarrow Y$ and $X \rightarrow \bar{Y}$ ($P_{15} = 1$),
- Discriminant in the case of large data ($P_{19} = 1$).

Due to the set of satisfied properties, we can give a first semantic for C_6 class. These measures are a standardized indices since they have a fixed values for the independence ($P_7 = 1$) and logical implication ($P_8 = 1$) case and the values taken by these indices to determine whether the rule is in the attractive ($P_{10} = 1$) or in the repulsive area ($P_{11} = 1$).

Figure 3 enables to verify the first semantic given to these indexes. We traced the evolution of the five measures when the number of examples increases starting then from the incompatibility state (no individual checks both the premise and the conclusion or also $n_{XY} = 0$, with n_{XY} the number of individuals verifying both the premise X and conclusion Y) to the logical implication (The set of individuals verifying the premise is included in the set of individuals satisfying the conclusion or also $n_{XY} = n_X$ with n_X the number of individuals satisfying

Fig. 3. Evolution of the five measures of C_6 class according to the number of examples.

the premise X). As well, we have shown in *figure 3* the three characteristic states of a rule: the incompatibility, independence and logical implication in addition to the attraction and repulsion areas. The whole premise size used to carry out these curves is 174, the overall conclusion size is 400 and finally the dataset size is 600 ($n_X = 174$, $n_Y = 400$ and $n = 600$). We could have chosen different sizes for these different sets and would have obtained similar curves observed with the following constraint: $n_X \leq n_Y \leq n$.

Property	Zhang	MGK	Yule'Y	Yule'Q	Good	C6
P_1	1	1	0	0	0	?
P_2	1	1	1	1	1	1
P_3	1	1	1	1	1	1
P_4	1	1	1	1	1	1
P_5	1	1	1	1	1	1
P_6	0	0	0	0	0	0
P_7	1	1	1	1	1	1
P_8	1	1	1	1	1	1
P_9	0	0	0	0	0	0
P_{10}	1	1	1	1	1	1
P_{11}	1	1	1	1	1	1
P_{12}	2	1	0	2	1	?
P_{13}	1	0	1	1	0	?
P_{14}	0	0	1	1	1	?
P_{15}	1	1	1	1	1	1
P_{16}	0	0	1	1	1	?
P_{17}	0	0	0	0	0	0
P_{18}	0	0	0	0	0	0
P_{19}	1	1	1	1	1	1

Table 4. Evaluation of properties on the measures of Class 6.

Figure 3 allows us to refine the semantic given to this class C_6 . These are standardized measures with values between -1 and 1 with fixed values equal to -1 , 0 and 1 respectively for the incompatibility, independence and logical implication. Moreover, they don't have only identifiable values in the attraction and repulsion area, but these values are between 0 and 1 in the attraction area and between -1 and 0 in the repulsion area. Finally, the measure sign provides information about the area belonging to the rule. We can deduce that these measures assess a certain distance according to the independence: distance between the independence and the logical implication in case of positive values and a distance between independence and incompatibility in case of negative values.

When we look at the figure showing the hierarchical clustering technique, we have a greater proximity between the indices Y, Q Yule and Goodman, and also higher proximity between Zhang and MGK. Discrepancies highlighted in the table, that is to say where we find the symbol "?" for the studied properties, we can learn about these two proximities more pronounced between the measures. Table 4 details the various properties satisfied by the five measures in this group and remember the general characteristics of this class. The first property where this symbol appears and which enables to explain these two proximities is the symmetry of measures (P_1). Y, Q Yule and Goodman are symmetric measures

(similar assessment of the symmetrical rules $X \rightarrow Y$ and $Y \rightarrow X$: $P_1 = 0$) while Zhang and MGK are not symmetric measures (different evaluation of the symmetric rules $X \rightarrow Y$ and $Y \rightarrow X$: $P_1 = 1$).

Properties P_{14} (opposed values or not for the rules $X \rightarrow Y$ and $\bar{X} \rightarrow Y$) and P_{16} (identical values for the rules $X \rightarrow Y$ and $\bar{X} \rightarrow \bar{Y}$ or not) also help to explain these two proximities. Indices Y, Q and Goodman have opposite values for the rules $X \rightarrow Y$ and $\bar{X} \rightarrow Y$ and identical values for the rules $X \rightarrow Y$ and $\bar{X} \rightarrow \bar{Y}$. The measures Zhang and MGK verify the negation of the two latter properties.

We will now make a study of class C_4 .

9.2. Study of the C_4 class

Class C_4 contains the following indexes: *Accuracy* (Tan et al, 2002), *Jaccard* (Jaccard, 1908), *Support* (Russell and Rao, 1940), *Cosine* (Ochiai, 1957), *Recall* (Lavrac et al, 1999), *Causal dependency* (Tan et al, 2002), *Causal confidence* (Kodratoff, 2001), *Causal-confirm confidence* (Kodratoff, 2001), *Negative reliability* (Lavrac et al, 1999), *Leverage* (Piatetsky-Shapiro, 1991), *Specificity* (Tan et al, 2002), *Czekanowski-Dice* (Czekanowski, 1913) and *Kulczynski* (Kulczynski, 1928).

From table 3, these 14 measures satisfy the 12 following properties:

- Non symmetry in the sense of conclusion negation ($P_2 = 1$),
- Discriminant in the case of large data ($P_{19} = 1$),
- Non Fixed value in the independence case ($P_7 = 0$) and equilibrium ($P_9 = 0$),
- Unidentifiable values in the case of attraction ($P_{10} = 0$) and repulsion ($P_{11} = 0$),
- Non-invariant in the case of expansion of certain numbers ($P_{13} = 0$),
- Two relations between the different negative rules are not present ($P_{14} = 0$) ($P_{15} = 0$),
- Not based on a probabilistic model ($P_{17} = 0$),
- Descriptive measures ($P_{18} = 0$).

Let us study now the properties satisfied by almost all the measures except one:

- Growth according to the number of examples ($P_4 = 1$) with the exception of the *Support*,
- Growth according to the size of the conclusion ($P_6 = 1$) with the exception of the *Support*,
- Measures do not equalize the rules $X \rightarrow Y$ and $\bar{X} \rightarrow \bar{Y}$ ($P_{16} = 0$) with the exception of *Accuracy*.

Given the relatively large number of the measures present in this class (the class whose cardinality is greater), it is difficult to find a semantic as precise as for the previous class C_6 . However, we can give one to a smaller set of measures: *Jaccard*, *Support*, *Cosine*, *Czekanowski-Dice*, *Kulczynski* and *Recall*. These measures are function $P(XY)$ and symmetrical (with the exception of the Recall). We recall the expressions of these *six* measures:

Prop	Jac	Supp	Cos	Rec	Czek	Kulc	Sub-set
P_1	0	0	0	1	0	0	0?
P_2	1	1	1	1	1	1	1
P_3	0	0	0	0	0	0	0
P_4	1	0	1	1	1	1	1?
P_5	0	0	0	0	0	0	0
P_6	1	0	1	1	1	1	1?
P_7	0	0	0	0	0	0	0
P_8	0	0	0	0	0	0	0
P_9	0	0	0	0	0	0	0
P_{10}	0	0	0	0	0	0	0
P_{11}	0	0	0	0	0	0	0
P_{12}	0	1	1	1	1	0	?
P_{13}	0	0	0	0	0	0	0
P_{14}	0	0	0	0	0	0	0
P_{15}	0	0	0	0	0	0	0
P_{16}	0	0	0	0	0	0	0?
P_{17}	0	0	0	0	00	0	0
P_{18}	0	0	0	0	0	0	0
P_{19}	1	1	1	1	1	1	1

Table 5. Evaluation of properties on a subset of measures of Class 4.

- *Jaccard* : $\frac{P(XY)}{P(X)+P(Y)-P(XY)} = \frac{P(XY)}{P(XY)+P(Y)}$
- *Support* : $P(XY)$
- *Cosine* : $\frac{P(XY)}{\sqrt{P(X)P(Y)}}$
- *Czekanowski – Dice* : $\frac{2P(XY)}{P(X)+P(Y)}$
- *Kulczynski* : $\frac{P(XY)}{P(XY)+P(XY)}$
- *Recall* : $\frac{P(XY)}{P(Y)}$

We can then deduce that these measures will have a fixed value equal to 0 in the case of incompatibility ($P(XY) = 0$). We also understand the non growth that is founded according to the dataset size ($P_5 = 0$) at the sight of these different formulas as shown in *table 5* which reproduces the satisfied properties by these *six* measures. We have an invariance of these measures (*except for the Support*) depending on the size n of the dataset since it amounts to increase the probability $P(XY)$. As to the *Support*, it is decreasing according to the size n of the whole data.

As with the previous class C_6 , we will study the evolution of these different

measures according to the number of examples. *Figure 4* restitutes this evolution. We retained the same cardinality as above for the sets premise, conclusion and the whole data set ($n_X = 174$, $n_Y = 400$ and $n = 600$).

We test the null value taken by these measures in the case of incompatibility. We obtain two types of curves:

- A straight line for the measures *Support*, *Cosine*, *Czekanowski-Dice* and *Recall*,
- A half-parabole for the measures *Jaccard* and *Kulczynski*.

After studying more precisely some classes and tried to give an interpretation to them, now we validate our work by a comparison with existing classifications (Vaillant, 2006), (Lesot and Rifqi, 2010), (Zighed et al, 2011), (Heravi and Zaïane, 2010).

10. Validation

Many studies have been realized to better understand interestingness measure behavior. In this section, we want to compare clusters of measures we obtained with previous works (Vaillant, 2006), (Huynh et al, 2007), (Y. Le Bras, 2011), (Lesot and Rifqi, 2010), (Zighed et al, 2011) in order to highlight similarities and differences between them.

10.1. Comparison with the work of B. Vaillant

We first compare the classification we obtained with that of Benoît Vaillant (Vaillant, 2006), who made his study on 20 measures according to 9 formal properties. From these nine properties, we have 7 properties in common as "*comprehensibility of the measure*" and "*easiness to set a threshold of acceptance*" are considered too subjective. To perform a classification, Benoît Vaillant also used Ward criterion but has retained Manhattan distance. The author points out that by using other criteria, he obtained similar results. He identified the five following classes:

- $ClBV_1 = \{\textit{Support}, \textit{Least contradiction}, \textit{Laplace}\}$,
- $ClBV_2 = \{\textit{Confidence}, \textit{Sebag}, \textit{Examples rate}\}$,
- $ClBV_3 = \{\textit{Correlation coefficient}, \textit{Piatetsky-Shapiro}, \textit{Pavilion}, \textit{Interest}, \textit{Implication index}, \textit{Cohen}, \textit{Informational gain}\}$,
- $ClBV_4 = \{\textit{Loevinger}, \textit{Bayes factor}, \textit{Conviction}\}$ and
- $ClBV_5 = \{\textit{Zhang}, \textit{IIET}, \textit{Intensity of implication}, \textit{Probabilistic Discriminant index}\}$.

We can assimilate *IIET* measure with *REII* because the purpose of both of them is the same.

We agree on the following grouping:

$$ClBV_2 \subset C_5, ClBV_4 \subset C_7,$$

and we have the following relations between groups: $ClBV_1 - \textit{Support} \subset C_5$, $ClBV_3 - \textit{Implication index} \subset G_{p8} \cup C_7$ and $ClBV_5 - \textit{Zhang} \subset C_1 \cup C_2$.

The grouping where the disagreement is the most important is $ClBV_3$, since we have bring up G_{p8} group which is present with only one technique: a version

Fig. 4. Evolution of the six measures of C_4 class according to the number of examples.

of k -means. As for $CUBV_5$ group, it includes all intensity of implication family measures, except Zhang measure.

We studied 12 additional properties, which explains why we do not find all the results of Benoît Vaillant.

In the following, we compare our results with those obtained by Y. Le Bras (Y. Le Bras, 2011).

10.2. Comparison with the work of Y. Le Bras

In his work, Y. Le Bras (Y. Le Bras, 2011) seeks to find common characteristics of objective measures. For that, he studied 42 interestingness measures according to six operational criteria that he proposed. These criteria concern from one hand the possibility to calculate robustness, and secondly to use efficient algorithms. Criteria are listed below:

- **Robustness measure calculation:** This is a rule measure resisting test w.r.t database disturbance (Le Bras et al, 2010)
 1. *Planar measure*: for some measures, distance calculation is reduced to the calculation of the distance to a plan, which allows to provide exact algebraic solution;
 2. *Quadratic measure*: measures require to use a certain number of mathematical tools.
- **Algorithmic properties** allowing algorithm to be effective:
 3. *GUEUC*: it is the general property UEUC (*Universal Existential Upward Closure*), which is a down monotonicity property;
 4. Measure *omni-monotony*;
 5. Measure *opti-monotony*;
- **Anti-monotony property** of a measure for finding optimal rules:
 6. Measure *anti-monotony*.

For each of the algorithmic properties, a generalization has been provided by the author (*GUEUC*, *omni-monotony* and *opti-monotony*) as he proposed existence conditions of these generalizations .

By looking to the 6 described properties, we find that we are in total disagreement with Y. Le Bras w.r.t criteria choosen for studying measures behavior. Nevertheless, this does not prevent us from confronting our two works for a better understanding of measures behavior. In total, we have 38 common measures, some of them have the same definition but with different names ³. By comparing our works, we seek to identify whether common measures which belong to the same group evaluate properties studied by (Y. Le Bras, 2011) in the same way.

The comparison of our results (*section 8*) with those obtained by Y. Le Bras reveals similarities according to these groups of measures.

- **C₃**: clusters Coverage, Gini, Implication index, J-measure, Prevalence and Pearl (which according to k-means, belongs to this group) measures, common to both works. According to (Y. Le Bras, 2011), none of these measures is quadratic or anti-monotonic. He also shows the closeness of Coverage and Prevalence measures, since they are the only two planar and omni-monotonic measures having GUEUC property;
- **C₄**: contains the following common measures Cosine, Czekanowski-dice, Jaccard, Kulczynski, Accuracy, Specificity, Support and Recall. All of them, except Cosine which is quadratic, are planar and verify the antimonotony property. Furthermore, we find that most of these measures have GUEUC property,

³ Interest represents Pearl in our work, Levier represents Novelty measure and J1-measure is Two-way support measure

- except Kulczynski and Specificity. Support is the only omni-monotonic measure in this cluster;
- C_5 : we remark that Descriptive confirmation is the only measure absent from this group. Y. Le Bras’s work (Y. Le Bras, 2011) reveals that Examples rate, Sebag, Ganascia and Confidence verify all the studied properties in the same way. Otherwise, none of C_5 commun measures is quadratic, but they all are omni and opti-monotonic. We realize also that all these measures are planar, except Laplace and that only two of them (Least contradiction and Laplace) are anti-monotonic;
 - C_6 : we find the following three opti-monotonic measures Y, Q Yule and Zhang, which do not check any of these properties, antimonotony, omni-monotony and planar measure. Visualizing the behavior of Piatetsky-shapiro and Novelty measures, which belong to this group according to the hierarchical method, we find that they are also opti-monotone and do not check the omni-monotony property and planar measure. Novelty, which seems to be more robust than Piatetsky-Shapiro (it is quadratic), is the only measure which has the good property of anti-monotonicity in class rules case;
 - C_7 : all C_7 measures have been studied by (Y. Le Bras, 2011), including Collective strength, Cohen and Odds ratio measures, which according to the hierarchical method belong to C_7 . Among all these measures, only Cohen is anti-monotonic, but none of them is omni-monotonic or planar. GUEUC property is verified by Pavilion, Conviction, Factor of Bayes, Informational gain, Interest and Loevinger, which are quadratic and opti-monotonic, identifying then strong operational properties with Cohen, Odds ratio and Relative risk measures.

Following our works comparison, we notice that from Y. Le Bras study on interestingness measures according to the six proposed criteria, we can identify behavior similarities between common measures of the same group. The only group which doesn’t reveal a good agreement is C_3 .

Another classification realized by (Huynh et al, 2007) on interestingness measures using datasets is presented in the next section and compared with the classification obtained in *section 8*.

10.3. Comparison with the work of Hyunh et al.

Another classification was made by Huynh et al. (Huynh et al, 2007), who studied 36 interestingness measures, with 32 commun measures, on 2 datasets with opposite nature: one highly correlated (mushroom) and the other weakly correlated synthetic base (T5.I2.D10K). authors present initially a taxonomy of measures according to the following 2 criteria:

1. *Topic*: deviation from independence or equilibrium;
2. *Nature*: descriptive or statistical.

From the study of these two particular parameters on datasets, the 5 following groups of measures are retained:

- Cl_{de} (*descriptive / deviation from equilibrium*): { *Confidence, Laplace, Sebag, Examples rate, Descriptive confirmation, Descriptive confirmed-confidence, Least contradiction* };

- Cl_{di} (descriptive / deviation from independence): { *Correlation*, *Interest*, *Loevinger*, *Conviction*, *Dependency*, *Pavillon*, *J-measure*, *Gini*, *TIC*, *Collective strength*, *Odds ratio*, *Yule's Q*, *Yule's Y*, *Klosgen*, *Cohen* };
- Cl_{se} (Statistical / deviation from equilibrium): { *IPEE* };
- Cl_{si} (Statistical / deviation from independence): { *II*, *EII*, *EII2*, *Lerman*, *Interest Rule* };
- Cl_o (other): { *Support*, *Precision*, *Jaccard*, *Cosine*, *Causal confidence*, *Causal confirmation*, *Causal confirmed-confidence*, *Causal dependency* }.

By comparing these 5 groups of measures with those described in Figure 2, we note our agreement on the categorization of the following measures: { *Confidence*, *Laplace*, *Sebag*, *Examples rate*, *Least contradiction* } $\subset C_5$, { *Correlation*, *Cohen*, *Collective strength*, *Odds ratio* } $\subset Gp_8$ since they are gathered according to the partitioning method *K-means*, { *Gini*, *J-measure*, *Dependence*, *Klosgen* } $\subset C_3$, { *Interest*, *Loevinger*, *Conviction*, *Pavillon*, *Klosgen* } $\subset C_7$, { *Yule's Q*, *Yule's Y* } $\subset C_6$ and finally { *Jaccard*, *Cosine*, *Causal confirmation*, *Causal Confidence*, *Causal confirmed-confidence* } $\subset C_4$. According to this comparison, we highlight similarities between groups of common measures revealed by both works.

10.4. Comparison with other works

Another classification was performed on distance and similarity measures by Marie-Jeanne Lesot and Maria Rifqi (Lesot and Rifqi, 2010). Authors studied the induced order using measures and not the obtained numerical values, since their context of study is the information research. This study focused on measures dedicated to binary and digital data by conducting experiments on both real and artificial data. The authors obtained a list of equivalent measures (measures that induce always the same order) and for non-equivalent measures, they quantified the disagreement by a degree of equivalence based on the generalized Kendall's coefficient. On the 10 measures studied and designed for binary data, five are common to our two studies. These measures are: *Czekanowski-Dice*, *Jaccard*, *Ochiai*, *Yule's Y* and *Yule's Q*. Authors found that *Yule's Y* and *Yule's Q* are equivalent measures. This result is also confirmed by our study since these two measures are in the same class C_6 as we have already mentioned, and are very close according to the dendrogram of the figure 1. They also found that *Czekanowski-Dice* and *Jaccard* are equivalent measures. Both measures were also assigned to the same class: the class C_4 , and we find them with a relatively large proximity in the dendrogram of the figure 1 (we chose *Cosine* measure as a representative one on the dendrogram as we have discussed in Section 4, *Cosine* and *Czekanowski-Dice* measures have identical values for the 19 properties which led to the formation of G_3 group). Finally, we grouped also *Ochiai* (or *Cosine*) measures with *Czekanowski-Dice* and *Jaccard* in C_4 cluster. Authors (Lesot and Rifqi, 2010) found a degree of equivalence between *Ochiai* measure and the equivalence class *Czekanowski-Dice*, *Jaccard* of 0.99, which confirms our results.

A final classification was proposed by Djamel Zighed, Rafik Abdesselam and Ahmed Bounekkar (Zighed et al, 2011) on 13 proximity measures. Only two of them are common to our two studies: *Cosine* and *Correlation coefficient*. The classification they proposed is based on the topological equivalence and uses the structure of local neighborhood. Both measures appeared very close in this

classification, in contrast to our work as we find them in classes C_4 and Gp_8 . The set of studied measures are so different, the founded classes by each technique are difficult to compare. Moreover, as authors emphasized during the presentation of their work, the classification they obtained is performed as poorly representative because it is applied on a single dataset: Fisher’s Iris.

We are well aware that measures categorization may also depend on several factors including: the data, the expert user, the nature of the extracted rules and classes search procedure, as highlighted by (Suzuki, 2008). To avoid bias data, the expert and the nature of the extracted rules, we have chosen here a theoretical study based on properties of measures, rather than experimental data (Huynh et al, 2005). Both are obviously complementary.

To avoid the bias of the clusters construction procedure, we used two classification techniques, which generally exhibited strong similarities between many measures, and highlights similarities and differences with previous works ((Vaillant, 2006), (Lesot and Rifqi, 2010), (Zighed et al, 2011)). This study complements previous works on the description of a unifying vision of interestingness measures (Hébert and Crémilleux, 2007), and adds a further contribution to the analysis of these measures.

11. Conclusion

This article takes as its starting point a synthesis paper on interestingness measures present in the literature to extract knowledge and properties judged relevant to them. This synthesis work led to the assessment of 19 properties judged interesting on 61 measures. The objective of this paper is the classification of these measures to assist the user in his choice of complementary measures to the couple (*Support*, *Confidence*) to eliminate uninteresting rules. Initially, we analyzed these data (matrix of 61 *measures* $\times$ 19 *properties*) to determine if simplification was not feasible by looking first to groups of measures with completely identical behavior and then by detecting if properties were not redundant. We detected seven groups of measures with completely identical behavior which enabled to reduce our starting data for the classification research by two techniques: a method of agglomerative hierarchical classification and a version of k -means method. Classifications obtained from both techniques allowed to reach a consensus: 7 classes were partially validated by existing classifications.

In the future, we would like to consolidate classes of measures we obtained by comparing the N best extracted rules in different databases and by each of the studied measures to verify that this set of N best rules is substantially the same in each class. Finally, it would be interesting to consider smaller classes (*with the help of the extracted dendogram*) to assign a semantic to each of them, which would be a great help to the user (*rather than a set of verified properties*), since we saw our inability to define in a few words or phrases each of these extracted classes. Complementary properties might to be considered. The notion of association rules robustness (Le Bras et al, 2010) could be also considered in the interestingness measures categorization.

12. Annexe 1

N^o	Measure	Formula
1	Correlation coefficient	$\frac{p(XY) - p(X)p(Y)}{\sqrt{p(X)p(Y)p(\bar{X})p(\bar{Y})}}$
2	Cohen or Kappa	$2 \frac{p(XY) - p(X)p(Y)}{p(X) + p(Y) - 2p(X)p(Y)}$
3	Confidence or precision	$\frac{p(XY)}{p(X)}$
4	Causal Confidence	$1 - \frac{1}{2} \left(\frac{1}{p(X)} + \frac{1}{p(Y)} \right) p(X\bar{Y})$
5	Centered Confidence or Pavillon	$\frac{p(XY)}{p(Y)} - p(Y)$
6	Descriptive Confirm Confidence or Ganascia	$1 - 2 \frac{p(X\bar{Y})}{p(X)}$
7	Causal Confirm Confidence	$1 - \frac{1}{2} \left(\frac{3}{p(X)} + \frac{1}{p(Y)} \right) p(X\bar{Y})$
8	Causal Confirm	$p(X) + p(Y) - 4p(XY)$
9	Descriptive Confirm	$p(XY) - p(XY)$
10	Conviction	$\frac{p(X)p(Y)}{p(XY)}$
11	Cosinus or Ochiai	$\frac{p(XY)}{\sqrt{p(X)p(Y)}}$
12	Coverage	$p(X)$
13	Czekanowski-Dice or F-measure	$2 \frac{p(XY)}{p(XY) + 1 - p(XY)}$
14	Dependency	$\ p(\bar{Y}) - \frac{p(X\bar{Y})}{p(X)}\ $
15	Putative Causal Dependency	$\frac{3}{2} + 2p(X) - \frac{3}{2}p(Y) - \left(\frac{3}{2p(X)} + \frac{2}{p(Y)} \right) p(X\bar{Y})$
16	Gray and Orłowska's Interestingness Weighting Dependency	$\left(\left(\frac{p(XY)}{p(X)p(Y)} \right)^k - 1 \right) \times p(XY)^m$
17	Bayes factor or Odd multiplier	$\frac{p(XY)p(Y)}{p(XY)p(Y)}$
18	Certainty factor or Loevinger or Satisfaction	$\frac{p(XY) - p(X)p(Y)}{p(X)p(\bar{Y})}$
19	Negative reliability	$\frac{p(X\bar{Y})}{p(\bar{Y})}$
20	Collective Strength	$\frac{p(XY) + \frac{p(X\bar{Y})}{p(X)}}{p(X)p(Y) + p(X)p(\bar{Y})} \times \frac{1 - p(X)p(Y) - p(X)p(\bar{Y})}{1 - p(XY) - \frac{p(X\bar{Y})}{p(X)}}$
21	Fukuda	$n \left(p(XY) - \sigma_c p(X) \right)$
22	Informational gain	$\log_2 \left(\frac{p(XY)}{p(X)p(Y)} \right)$
23	Gini	$p(X) \left(\frac{p^2(XY)}{p^2(X)} + \frac{p^2(X\bar{Y})}{p^2(X)} \right) + p(\bar{X}) \left(\frac{p^2(XY)}{p^2(\bar{X})} + \frac{p^2(X\bar{Y})}{p^2(\bar{X})} \right) - p^2(Y) - p^2(\bar{Y})$

24	Goodman-Kruskal	$\frac{\sum_j \max_k P(X_j, Y_k) + \sum_k \max_j P(X_j, Y_k) - \max_j P(X_j) - \max_k P(Y_k)}{2 - \max_j P(X_j) - \max_k P(Y_k)} \times$ $\frac{\frac{n_{XY} n_{\bar{X}\bar{Y}}}{n^2} - \frac{n_{X\bar{Y}} n_{\bar{X}Y}}{n^2}}{\frac{n_{XY} n_{\bar{X}\bar{Y}}}{n^2} + \frac{n_{X\bar{Y}} n_{\bar{X}Y}}{n^2}}$
25	Implication index	$\sqrt{n} \frac{p(XY) - p(X)p(Y)}{\sqrt{p(X)p(Y)}}$
26	Probabilistic intensity of deviation from equilibrium (IPEE)	$P \left[N(0, 1) \geq \frac{n_{X\bar{Y}} - n_{XY}}{\sqrt{n_{X\bar{Y}}}} \right]$
27	Entropic probabilistic intensity of deviation from equilibrium (IP3E)	$\sqrt{\left[\frac{1}{2} \left((1 - h_1(P(X\bar{Y}))^2) \times (1 - h_2(P(X\bar{Y}))^2) \right)^{\frac{1}{4}} + 1 \right]} \times$ $\sqrt{IPEE} \quad \text{with } h_1(t) = -\left(1 - \frac{t}{P(X)}\right) \log_2 \left(1 - \frac{t}{P(X)}\right) -$ $\frac{t}{P(X)} \log_2 \left(\frac{t}{P(X)}\right) \text{ for } t \in \left[0, \frac{P(X)}{2}\right], \text{ else } h_1(t) = 1 \quad h_2(t) =$ $-\left(1 - \frac{t}{P(Y)}\right) \log_2 \left(1 - \frac{t}{P(Y)}\right) - \frac{t}{P(Y)} \log_2 \left(\frac{t}{P(Y)}\right) \text{ for } t \in$ $\left[0, \frac{P(Y)}{2}\right], \text{ else } h_2(t) = 1$
28	Probabilistic discriminant index (PDI)	$P \left[N(0, 1) \geq II^{CR/B} \right] \text{ where } II^{CR/B} \text{ indicate that } II \text{ is}$ reduced-centred according to the values taken by II on the extracted rules set.
29	Mutual Information	$\frac{VS(XY)}{-P(X) \log_2 P(X) - P(\bar{X}) \log_2 P(\bar{X})}$
30	Intensity of Implication (II)	$P \left[Poisson(nP(X)P(\bar{Y})) \geq P(X\bar{Y}) \right]$
31	Entropic intensity of implication (IIE)	$\sqrt{\left[\left(1 - h_1(P(X\bar{Y}))^2\right) \times \left(1 - h_2(P(X\bar{Y}))^2\right) \right]^{\frac{1}{4}}} \times II$
32	Entropic intensity of revised implication (IIER)	$\sqrt{\left[\left(1 - h_1(P(X\bar{Y}))^2\right) \times \left(1 - h_2(P(X\bar{Y}))^2\right) \right]^{\frac{1}{4}}} \times$ $\sqrt{\max(2 \times II - 1; 0)}$
33	Likelihood discriminant index	$P \left[Poisson(nP(X)P(Y)) < P(XY) \right]$
34	Interest or Lift	$\frac{p(XY)}{p(X)p(Y)}$
35	Jaccard	$\frac{p(XY)}{p(XY) + p(Y)}$
36	J-Measure	$p(XY) \log \left(\frac{p(XY)}{p(X)p(Y)} \right) + p(X\bar{Y}) \log \left(\frac{p(X\bar{Y})}{p(X)p(Y)} \right)$
37	Kloggen	$\sqrt{p(XY)} \left(\frac{p(XY)}{p(X)} - p(Y) \right)$
38	Kulczynski or Agreement and disagreement index	$\frac{p(XY)}{p(X\bar{Y}) + p(\bar{X}Y)}$
39	Laplace	$\frac{np(XY) + 1}{np(X) + 2}$
40	Leverage	$\frac{p(XY)}{p(X)} - p(X)p(Y)$
41	M_{GK}	$\text{If } P(Y/X) \geq P(Y) \text{ then } M_{GK}(X \rightarrow Y) =$ $\frac{p(Y/X) - p(Y)}{1 - p(Y)} \text{ Else } M_{GK}(X \rightarrow Y) = \frac{p(Y/X) - p(Y)}{p(Y)}$
42	Least contradiction or Surprise	$\frac{p(XY) - p(XY)}{p(Y)}$

43	Novelty	$p(XY) - p(X)p(Y)$
44	Pearl	$p(X) \frac{p(XY)}{p(X)} - p(Y) $
45	Piatetsky-Shapiro	$n \times \left(p(XY) - p(X)p(Y) \right)$
46	Accuracy	$p(XY) + p(XY)$
47	Prevalence	$p(Y)$
48	Yule's Q	$\frac{p(XY)p(X\bar{Y}) - p(X\bar{Y})p(XY)}{p(XY)p(X\bar{Y}) + p(X\bar{Y})p(XY)}$
49	Recall	$\frac{p(XY)}{p(Y)}$
50	Odds Ratio	$\frac{p(XY)p(X\bar{Y})}{p(X\bar{Y})p(XY)}$
51	Relative Risk	$\frac{p(Y/X)}{p(Y/\bar{X})}$
52	Sebag-Schoenauer	$\frac{p(XY)}{p(XY)}$
53	Specificity	$\frac{p(XY)}{p(X)}$
54	Support or Ruesel and Rao index	$p(XY)$
55	Yao and Liu's One Way Support	$\frac{p(XY)}{p(X)} \log_2 \frac{p(XY)}{p(X)p(Y)}$
56	Yao and Liu's Two Way Support	$p(XY) \log_2 \frac{p(XY)}{p(X)p(Y)}$
57	Examples and counter-examples rate	$\frac{p(XY) - p(X\bar{Y})}{p(XY)}$
58	Test value VT100	$\phi^{-1}(P[\text{Hypergeometric}(100P(X)P(Y)) \leq P(XY)])$
59	Yao and Liu's Two Way Support Variation	$p(XY) \log_2 \frac{p(XY)}{p(X)p(Y)} + p(X\bar{Y}) \log_2 \frac{p(X\bar{Y})}{p(X)p(Y)} +$ $p(\bar{X}Y) \log_2 \frac{p(\bar{X}Y)}{p(X)p(Y)} + p(\bar{X}\bar{Y}) \log_2 \frac{p(\bar{X}\bar{Y})}{p(X)p(Y)}$
60	Yule's Y	$\frac{\sqrt{p(XY)p(X\bar{Y})} - \sqrt{p(X\bar{Y})p(XY)}}{\sqrt{p(XY)p(X\bar{Y})} + \sqrt{p(X\bar{Y})p(XY)}}$
61	Zhang	$\max \left\{ p(XY)p(\bar{Y}), p(Y)p(X\bar{Y}) \right\}$
